

**Amendments to the Claims**

1. (Currently Amended) A method for communicating information over a WDM fiber optical ring network in a metro access area using one or more wavelengths which can be shared by a plurality of user terminals, each user terminal in said plurality of user terminals coupled to an end station, comprising the steps of:

sending at least one downstream data packet;  
sending at least one optical chalkboard packet consisting of a recognizable pattern; and  
sending a control signal.

2. (Original) The method according to claim 1, further comprising the steps of:  
reading, by the end station, data packets addressed to said end station;  
passing packets not addressed to said end station through semiconductor optical amplifiers (SOAs); and  
writing data onto said optical chalkboards when permitted to do so by said control signals.

3. (Canceled)

4. (Canceled)

5. (Canceled)

6. (Canceled)

7. (Original) The method according to claim 2, wherein the reading step further comprises the steps of:  
tapping a portion of light for a receiver;  
decoding, by said receiver, downstream packets; and  
passing a remaining portion of light to a wavelength-independent and polarization independent modulator.

8. (Original) The method according to claim 2, wherein the reading step further comprises the steps of:

tapping a portion of light for a receiver;  
decoding, by said receiver, downstream packets; and  
passing a remaining portion of light to a polarization independent modulator.

9. (Original) The method according to claim 2, wherein the reading step further comprises the steps of:

tapping a portion of light for a receiver;  
decoding, by said receiver, downstream packets; and  
passing a remaining portion of light to a wavelength-independent modulator.

10. (Original) The method according to claim 2, wherein said writing step further comprises the steps of:

determining when said control signals permit said writing; and  
writing data by modulating said optical chalkboard.

11. (Original) The method according to claim 2, further comprising the steps of:  
exiting said end station of light carrying data packets;  
re-entering an access node by light carrying data packets via a WDM fiber optical distribution ring; and  
continuing onto a WDM fiber optical feeder ring to a next node.

12. (Original) The method according to claim 11, wherein said next node is an access node.

13. (Original) The method according to claim 11, wherein said next node is a network node.

14. (Currently Amended) The method according to claim ~~10~~11, wherein said determining step is accomplished using a Media Access Control (MAC) protocol.

15. (Original) The method according to claim 2, further comprising the steps of:  
optically amplifying downstream data packets and any upstream data created by said  
writing step;

pre-equalizing any upstream data created by said writing step; and  
modulating any upstream data created by said writing step.

16. (Original) The method according to claim 14, wherein a FDDI standard protocol  
is modified and used as the MAC protocol.

17. (Original) The method according to claim 14, wherein an ADAPT standard  
protocol is modified and used as the MAC protocol.

18. (Original) The method according to claim 16, wherein said fiber optical feeder  
ring is unidirectional and further wherein said data packets transmitted through said next node  
are received by said next node and then forwarded when said next node gets a token, and further  
wherein said next node is a network node.

19. (Original) The method according to claim 16, wherein said fiber optical feeder  
ring is bi-directional, and further wherein a source transmits said data packets to a destination on  
one of a clockwise and counter-clockwise fiber.

20. (Original) The method according to claim 19, wherein a choice between  
transmitting on one of the clockwise and the counter-clockwise fiber is made such that the data  
packets reach said destination before reaching said next node, further wherein said next node is a  
network node.

21. (Original) The method according claim 17, wherein access nodes request  
bandwidth from said next node through a dedicated channel, and said next node grants  
bandwidth to access nodes according to a specified scheduling algorithm, and further wherein  
said next node is a network node.
